HydraGeneration Pale rose

The restoration of the hydrolipidic balance
Because skin hydration consists in a good balance between water and lipids in epidermis.
To keep longer a smoothier and a more supple skin.
And a better dehydration-fighter skin.

A STORY

The pale rose | Rosa centifolia, Rosaceae
An aromatic and universal beauty

Born in Caucasus and modified by several hybridizations, the pale rose got its name thanks to its flowers with double petals that exhal a strong fragrance in spring. Cultivated for its aromatic properties from the XIXth century, it has become one of the mainstays in the perfume industry. The empress Josephine owned 27 different species in the garden of her property la Malmaison. In Western world, its healing properties (antiseptic, astringent, depurative) have made the pale rose an element of the traditional pharmacopoeia.

Key points

An active plant cell
Developed to deliver the highest amount of original active molecules.

A high tech natural ingredient
Created to preserve and improve the identity and the benefits of a natural product.

An essential moisturizing action
Helps to moisturize on a short and long term, increases the protective function of skin.

PRODUCT BENEFITS

Hydrating

Moisturizing
Keeps water in the epidermis, stimulates NMF levels and the quality of the hydrolipid film in the corneous layer.

Regenerating
Increases epidermis cell regeneration and helps to rebuild the hydrolipidic film.

Protection
Reinforces the stratum corneum, helps to retore the skin barrier.

To be used in skincare or make-up products such as cream, fluid, serum, balm, lotion, milk, foundation, concealer, etc. In any colour cosmetic or skincare product dedicated to moisturizing skin.

HOW IT WORKS

HydraGeneration Pale rose: reinforces the natural mechanisms of water retention in the epidermis

HydraGeneration Pale rose acts quickly on the water circulating in epidermis by avoiding that it evaporates. In the same time, it restores the hydric circuit thanks to a stimulation of the cell renewal. Besides it contributes to the creation of lipids like free fatty acids, cholesterol, ceramids, etc., elements which are in the stratum corneum of the epidermis and help to keep corneocytes together. Those cells of the stratum corneum play precisely skin barrier part.

Thanks to that better hydrolipidic balance, epidermis limits dryness process and provides a better protection against outside aggressions.

Maintaining water in the epidermis

Skin contains between 60% to 80% water according to age; stratum corneum contains 13% to 15%. Skin is considered as hydrated when that percentage goes beyond 10%, and dehydrated when the percentage is below 10%, stratum corneum becomes rough, flaking and loses its integrity. Most water is actually in the dermis thanks to proteoglycans that are fixed to big quantities of water.

Therefore there are 2 types of water in the epidermis:
- A static water, that can’t move, located in stratum corneum, or called “water linked to corneocytes” thanks to the NMF (Natural Moisturizing Factor) and between corneocytes, where water is trapped by lipids, especially ceramides, that are located in the hydrolipidic film (cf. cell renewal). It gives elasticity and suppleness to skin.
- A dynamic water that moves, circulates from the dermis to the several layers of the epidermis, called also transepidermic flux. That water from the dermis is essential to the epidermis nutrition for the nutrients it brings. It helps to protection and homeostasis in the epidermis.

Water follows a path from beneath the skin to its surface, when it arrives at the surface, the water evaporates. This occurs at a rate of about 5g water/m²/hour.

As hydration state depends on the value of the transepidermic flux, on the balance between diffusion and evaporation, and the ability of stratum corneum to be fixed with water, Naolys studied both the action of HydraGeneration Pale rose on dynamic water and on static water in the epidermis, but also on the cohesion between corneocytes.

Strengthening the skin barrier

The epidermis, the superficial layer of skin is first made of cells called keratinocytes which renew non stop according to a 21 days cycle. That renewal of the epidermis is made thanks to the cell proliferation and the differenciation that keep the balance of adult tissues, therefore keratinocytes, divide at the level of the basal layer of the epidermis, which is mainly made of non differenciated cells and migrate to the surface changing their form: they lose their nuclei and load hard filaments of keratine. When they reach the cornified layer, they become corneocytes, dead cells that create a solid membran (thanks to keratine) impermeable and protective: the protective natural barrier of the epidermis. Those built up corneocytes will naturally break away and be shed.

Keratine contains several substances, especially the NMF (Natural Moisturizing Factor) between cells; it is a mix of hygroscopic substances that enable corneocytes to be fixed with water: free amin acids (40%), pyrrolidon carboxylic acid (12%), lactates (12%), urea, sugars and meral salts. In the same time, during the keratinisation process, keratinocytes release a fraction of epidermis lipids which, associated with the secretion of sebaceous glands and water coming from sudoral secretions, consist in a hydrolipidic film, an emulsion located in the stratum corneum.

By helping cell renewal, HydraGeneration Pale rose contributes not only to the production of keratine, which is like a barrier to skin. But also to the production of NMF and the hydrolipidic film. Both of them keep dynamic water diffused in the corneocytes inside epidermis.

Study of the proliferation and the differenciation of epidermis cells

In order to show that the balance of tissues has been maintained, Naolys studied both proliferation and differenciation of epidermis cell. KI67 is an anti-gene to mark cell proliferation and filaggrin is a protein to mark cell differenciation. Studies have been made on reconstructed epidermis.

<table>
<thead>
<tr>
<th>Study of epidermis cell proliferation</th>

<tr>
<td><strong>EPIDERMIS TREATED WITH HYDRAGENERATION PALE ROSE AT 2.5%</strong></td>
</tr>
</tbody>
</table>

Decrease of the epidermis differenciation

- Decrease of the epidermis differenciation that is translated by a decrease of the labelling of filaggrin that is less intense but uniform at the level of the granuleous layer.
